

ABSTRACT

A container has a disposable receptacle present within the container. The disposable receptacle, such as a suitably structured bag, is positioned within the
5 container, and an air eliminator eliminates air from a space that is between the bag and the container, so that the bag is pulled against an interior of the container, thereby reducing the flammability and puncture resistance of the bag. The bag has a closure mechanism that prevents air from entering the bag, and that prevents smoke from escaping from the bag, after a burning object is placed
10 within the bag.
